

WEEK 12 – TUTORIAL**Objectives:**

The objective of this tutorial is to develop a practical understanding of IT Service Management (ITSM) and its core practices, focusing on how they support organizations like universities or banks. Students will learn to differentiate ITSM from IT Project Management, identify applicable service relationship models (B2B, B2C, C2C, B2G, etc.), and apply key ITIL practices such as Incident and Problem Management in real-world contexts. Through case study analysis and workflow design, students will explore how incidents are reported, categorized, and resolved, how root causes are identified, and how continual improvement is achieved. The tutorial aims to help students connect theory to practice by understanding how structured ITSM processes, roles, and tools ensure efficient, reliable, and value-driven IT service delivery.

Tutorial Activities:

- Part A: Discussion
- Part B: Case study analysis

Learning outcomes

By the end of this tutorial, students will be able to:

- LO5. Demonstrate team and management skills.

Part A: Discussion

- Why is ITSM critical for organizations like universities or banks?
ITSM ensures reliable, consistent, and high-quality IT service delivery, essential for mission-critical operations. In universities, ITSM supports systems like LMS, email, and student portals that enable learning continuity. In banks, it ensures system uptime, security, and compliance. ITSM frameworks like ITIL provide structure for handling incidents, managing change, and driving continual improvement, thereby enhancing efficiency, user satisfaction, and trust.
- How does IT Project Management differ from ITSM, and where do they overlap?
IT Project Management focuses on delivering one-time initiatives (e.g., developing a new system) within defined scope, time, and cost. ITSM, on the other hand, manages ongoing IT services post-deployment, ensuring stability and value delivery. They overlap during project transition, when a completed project is handed over into service operations. Effective collaboration between both ensures smooth implementation and sustained service performance.
- Discuss which service relationship models (B2B, B2C, C2C, B2G, etc.) apply to IT services in a campus setting.
B2C (Business to Consumer): University IT provides services directly to students (e.g., LMS access, email).
B2B (Business to Business): University IT partners with vendors (e.g., Microsoft, Canvas).
B2E (Business to Employee): IT services for faculty and administrative staff.
B2G (Business to Government): When universities report IT compliance or data to government agencies.

C2C (Consumer to Consumer): Student forums or peer-learning platforms hosted on campus networks.

Part B: Case Study Analysis

Scenario:

Students are unable to access the LMS during exam week. Incidents are reported to the Service Desk. Some issues repeat, and IT staff are unsure about the root cause.

Based on the scenario, answer the following:

- Identify incidents vs problems.
Incidents: Individual reports from students unable to log in or access resources.
Problem: The underlying cause of recurring access failures (e.g., server overload, authentication error, or network congestion).
- Propose workarounds for immediate relief.
Enable temporary access through cached pages or backup servers.
Extend exam submission deadlines.
Communicate via alternate platforms (email, Teams).
Restart or scale up LMS instances temporarily.
- Suggest permanent fixes using Problem Management practices.
Conduct a root cause analysis (RCA) to identify underlying issues.
Implement preventive actions (e.g., load balancing, improved authentication).
Update documentation and configuration management database (CMDB).
Create a Known Error Record to prevent future disruptions.
- In groups, draw a simple Incident Management workflow for the LMS scenario:
 - Steps: User reports → Service Desk → Categorize → Assign → Resolve → Close → Continual Improvement.
 - Label tools, roles, and outputs at each step.

User reports: Student submits issue via portal/email.
Tool: ServiceNow or Jira Service Management
Role: End-user
Output: Incident ticket created

Service Desk: Logs, validates, and prioritizes incident.
Role: Service Desk Agent
Output: Categorized ticket

Categorize: Determines type (LMS access issue).
Output: Categorization data in system

Assign: Routes to appropriate team (Network or LMS admin).
Role: Incident Coordinator
Output: Assigned ticket

Resolve: Technical team fixes access or deploys workaround.

Role: Technical Support Team

Output: Resolved status update

Close: Service Desk verifies resolution with user and closes ticket.

Output: Closed record

Continual Improvement: Problem record reviewed to identify trends and prevent recurrence.

Tool: ITIL Continual Improvement Register

Output: Updated improvement plan
